Process for hydroxylating aromatic hydrocarbons

A process for the hydroxylation of aromatic hydrocarbons by means of hydrogen peroxide, consisting of reacting the compounds in the presence of synthetic zeolites containing either. substituted or exchanged heteroatoms. The reaction is carried out in acetone at a temperature of between 80 and 120°C.

SPECIFICATION

Process for hydroxylating ar matic hydrocarbons

This invention relates to a process for the hydroxylation of aromatic hydrocarbons.

The direct hydroxylation of aromatic hydrocarbons with hydrogen peroxide has been known for some time, and is carried out in the presence of a 10 catalyst which is generally chosen from transition metals.

However, this reaction has certain drawbacks, including a low selectivity with respect to the hydrogen peroxide because of the partial decom-15 position thereof by the metal ions; a low selectivity with respect to the reacted hydrocarbon because of coupling reactions of intermediate organic radicals; and, in the particular case of phenol, the fact that the diphenols which are formed are more easily oxidis-20 able than the phenol itself, resulting in an inevitable reduction in the extent of conversion.

In carrying out the reaction between an aromatic hydrocarbon and hydrogen peroxide, it is known to use an acid aluminosilicate which has been 25 poisoned or partly modified by a rare earth

(US-A-3580956).

Although improving the performance of the reaction, the use of this catalytic material does not however completely eliminate the production of 30 considerable quantities of useless by - products, the presence of which negatively influences the final results and the economy of the entire process.

From GB-A-2083816, it is known to be possible to bond hydroxyl groups to aromatic nuclei by reacting 35 the aromatic hydrocarbon concerned with hydrogen peroxide, with none of the aforesaid drawbacks, by carrying out the reaction in the presence of synthetic zeolites containing either substituted or exchanged heteroatoms. Zeolite materials which can be used in 40 this process can be chosen from, for example, those described in GB-A-2024790 and GB-A-2078704. which describe synthetic materials comprising crystalline silica modified by the presence of elements which enter the crystalline silica lattice in place of 45 silicon atoms. The modifying elements may be chosen from Cr, Be, Ti, V, Mn, Fe, Co, Zn, Rh, Ag, Sn, Sb and B. Also disclosed in GB-A-2024790 and GB-A-2078704 are methods for preparing these synthetic materials, and reference should be made 50 thereto for the necessary details and for a better understanding of the structure of the material itself.

Returning to the hydroxylation process, as disclosed in GB-A-2083816, it is important to emphasise the great advantage which derives from the use of 55 synthetic zeolites, this advantage consisting of the facility for guiding the reaction towards the formation of one product rather than other by simply choosing a determined modified zeolite. Thus, for example, in the case of phenol hydroxylation, there 60 may be used a porous crystalline synthetic material formed from silicon and titanium oxides, such as disclosed in GB-A-2071071. The use of such a material enables a mixture of hydroquinone and pyrocatechol in a ratio equal to or greater than 1:1 to 65 be obtained.

The reaction between the aromatic hydr carbon and hydrogen peroxide is preferably carried out at a temperature of from 80 to 120°C, in the presence of the hydrocarbon either alone or with a solvent 70 chosen from water, methanol, acetic acid isopropanol or acetonitrile. Examples of the aromatic hydro-

carbon are phenol, toluene, anisole, xylenes, mesitylene, benzene, nitrobenzene, ethylbenzene and acetanilide.

According to the present invention, there is provided a process for the hydroxylation of an aromatic hydrocarbon, which comprises reacting the aromatic hydrocarbon and hydrogen peroxide in the presence of a synthetic zeolite containing substituted and/or exchanged heteroatoms, the reaction being carried

out in the presence of acetone.

Thus, we have now found that by reacting the hydrocarbon concerned in the presence of acetone, e.g. as a solvent, it is possible to carry out the

85 reaction using high feed ratios and with high yields. The quantity of heavy by-products is usually very low. The reaction is preferably carried out at a temperature of from 80 to 120°C, more preferably carried out at the reflux temperature.

Examples of the aromatic hydrocarbon are those listed above.

In preferred embodiments, the synthetic zeolite is as claimed in any of claims 1 to 15 and 45 of GB-A-2024790, or as claimed in any of claims 1, 2 95 and 32 of GB-B-2024790, or as claimed in any of claims 1 to 7 and 29 of GB-A-2078704, or as claimed

in any of claims 1 to 6 and 28 of GB-B-2078704. The invention will now be illustrated by the following Examples, in which the following terms 100 are used:

3

```
Moles of H<sub>2</sub>O<sub>2</sub> fed
Feed ratio =
                              x 100
           Moles of phen I fed
                   Moles of diphenols formed
Phenol selectivity
                                            x 100
                   Moles of phenol reacted
                   Moles of diphenols formed
H<sub>2</sub>O<sub>2</sub> yield
                                            x 100

HMME

    hydroquinone monomethylether

                Moles of HMME formed + moles of guaiacol formed × 100.
Anisole yield
                            Moles of anisole reacted
       EXAMPLE 1
         50g of phenol, 39g of acetone and 2.5g of catalyst
       were fed into a 250 cc flask. When the system
       reached a temperature of 80°C, 10 cc of 36% w/v
       H<sub>2</sub>O<sub>2</sub> were added. The following results were
       obtained after two hours of reaction:
         Phenol conversion...... 18.36%
         Tarry by-product/tarry by-product + diphenols....... 4.2%
         Hydroquinone selectivity...... 50%
       FXAMPLE 2
         The procedure of Example 1 was repeated, but 15
        cc of 36% w/v H<sub>2</sub>O<sub>2</sub> were added. The following
        results were obtained after two hours:
         Phenol selectivity ...... 95.45%
         Phenol conversion...... 24,25%
         Tarry by-product/tarry by-product + diphenols....... 5.1%
         Hydroquinone selectivity...... 50%.
         The procedure of Example 2 was repeated, but 20
       cc of 36% w/v H<sub>2</sub>O<sub>2</sub> were added. The following
       results were obtained after two hours;
         Phenol selectivity ...... 92.96%
         Phenol conversion...... 31.28%
         Tarry by-product/tarry by-product + diphenols....... 7.8%
         Hydroquinone selectivity...... 50%.
       EXAMPLE 4
         The procedure of Example 3 was repeated, but 25
       cc of 36% H<sub>2</sub>O<sub>2</sub> were added. The following results
       are obtained after two hours:
         Phenol selectivity ...... 91.29%
         H<sub>2</sub>O<sub>2</sub> yield...... 68.9%
         Tarry by-product/tarry by-product + diphenols....... 9.7%
         Hydroquinone selectivity...... 50%
         Phenol conversion...... 36.64%.
         The procedure of Example 4 was repeated, but 30
       cc of 36% H<sub>2</sub>O<sub>2</sub> were added. The following results
       were obtained after two hours:
         Phenol selectivity ...... 89.4%
         Tarry by-product/tarry by-product + diphenols....... 12%
         Hydroquinone selectivity ...... 50%
```

Phenol conversion...... 37.76%.

EXAMPLE 6

30 cc fanisol , 70 cc of acetone and 3 g f cataiyst were fed into a 250 cc flask fitted with a bulb condenser. When a temperature of 70° C was reached, 7.5 cc of 36% H_2O_2 were added in drops. The following results were obtained on termination of the reaction;

OI LIE IEBULOII,		
Product distribution:	HMME	64%
	Guaiacol	36%
	———	
H ₂ O ₂ yield	*************************************	72.8%
Anisole conversion		22.7%
Tarry by-product/tarry by-product + phenol product		6.26%
Tarry by-production	Dy product : priorite pro-	OD 6%
Anisole yield		30.078.
EXAMPLE 7		
The procedure of example 6 was repeated, but 10		
cc of 36% H ₂ O ₂ were add	ged. The results are as	
follows:		
Product distribution:	HMME	64%
1,00001 2.00.00000	Guaicol	36%
	•	
	*************	70%
Anisol vield	*******************************	86%
		24%
Anisole conversion		
Tarry by-product/tarry by-product + phenol product 1		

The catalyst used in all of the above Examples is a titanium silicalite prepared as described in Example 1 of GB-A-2071071.

CLAIMS

- A process for the hydroxylation of an aromatic hydrocarbon, which comprises reacting the aromatic hydrocarbon and hydrogen peroxide in the presence of a synthetic zeolite containing substituted and/or exchanged heteroatoms, the reaction being carried
 out in the presence of acetone.
 - A process according to claim 1, wherein the aromatic hydrocarbon is phenol, toluene, anisole, a xylene, misitylene, benzene, nitrobenzene, ethylbenzene, or acetanilide.
- 15 3. A process according to claim 1 or 2, wherein the reaction is carried out at a temperature of from 80 to 120°C.
 - 4. A process according to claim 1, 2 or 3, wherein the synthetic zeolite is as clamed in any of claims 1
- 20 to 15 and 45 of GB-A-2024790, or as claimed in any of claims 1, 2 and 32 of GB-B-2024790.
- A process according to claim 1, 2 or 3, wherein the synthetic zeolite is as claimed in any of claims 1 to 7 and 29 of GB-A-2078704, or as claimed in any of 25 claims 1 to 6 and 28 GB-B-2078704.
 - A process according to claim 1, 2 or 3, wherein the synthetic zeolite is as claimed in any of claims 1 to 5 and 27 of GB-A-2071071 or GB-B-2071071.
- A process acc. claim 1, substantially
 as described in any or the foregoing Examples.
 - 8. A hydroxylated aromatic hydrocarbon when produced by a process according to any of claims 1 to 7.
